X-Pinch of Mega-Ampere-Range

Current amplitude:

up to 2.3 MA

Materials:

W, Mo, nichrome, stainless steel

Number of wires:

from 2 to 20

Linear mass m_l :

from 3.7 to 40 mg/cm

Diagnostic setup

- Three pin-hole cameras with X-ray filters
- X-ray spectrograph for 1.5-8 keV range
- Measurement of X-ray power in different spectral range (100 eV - 1 MeV)
- Visible light registration in chronographic and frame regimes

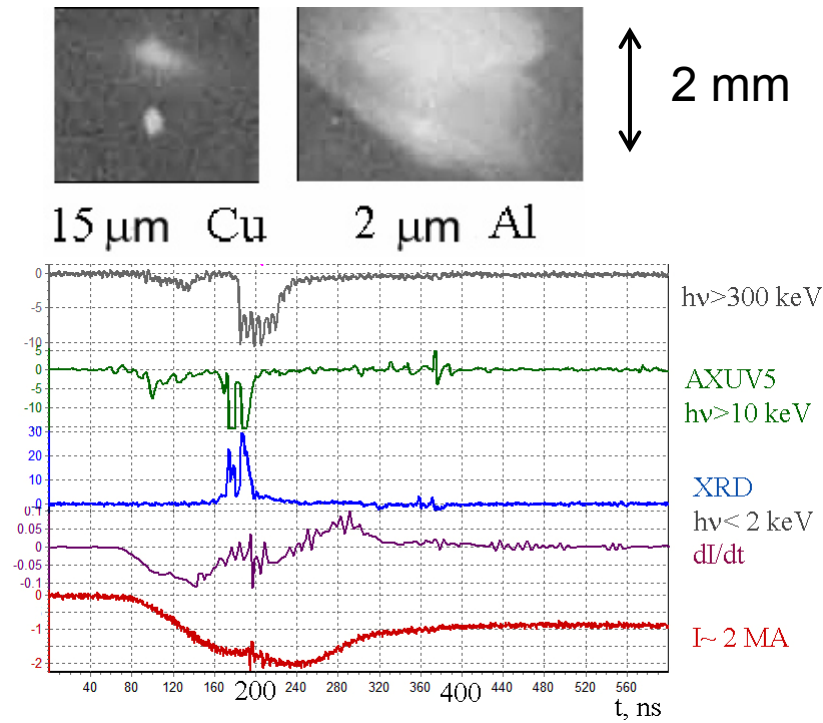

Diagnostic capabilities

- Time-integrated measurements of dimensions in soft X-ray range $\Delta x \sim 5 \mu\text{m}$
- Frames in soft X-ray $\Delta x \sim 0,3 \text{ mm}$, $\Delta t \sim 5 \text{ ns}$
- Time-integrated X-ray spectrograph $h\nu \sim 1,5\text{--}8 \text{ keV}$, $\lambda/\delta\lambda \sim 300$
- Frames in visible light $\Delta t \sim 0,5 \text{ ns}$ and $\Delta t \sim 5 \text{ ns}$
- Streak in visible light $\Delta t \sim 5 \text{ ns}$, $\Delta x \sim 0,3 \text{ ns}$
- X-ray power:

$h\nu \sim 1\text{--}3 \text{ keV}$	$\Delta t \sim 1 \text{ ns}$
$h\nu \sim 3\text{--}40 \text{ keV}$	$\Delta t \sim 2 \text{ ns}$
$h\nu \sim 60\text{--}1000 \text{ keV}$	$\Delta t \sim 4 \text{ ns}$

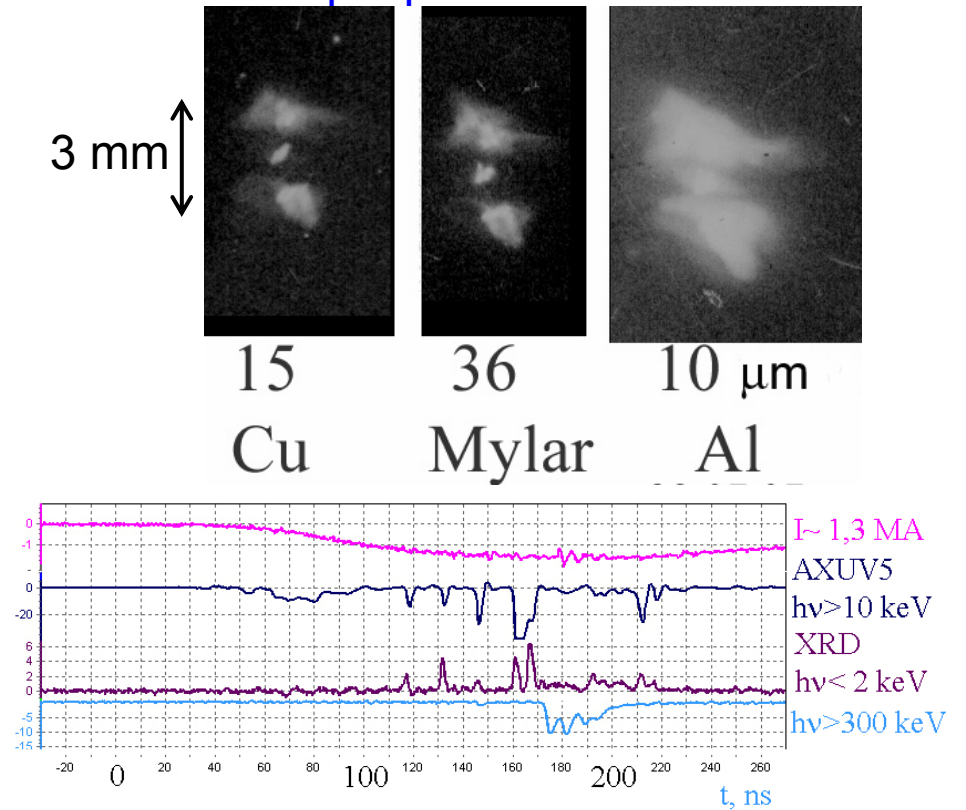

Experimental result at 1.3-2.3 MA currents

Several pulses

$I_{max} \sim 2.0 \text{ MA}$
 stainless steel: 16*100 μm
 $m_l \sim 10 \text{ mg/cm}$

Multiple pulses

$I_{max} \sim 1.3 \text{ MA}$
 stainless steel: 12*100 μm
 $m_l \sim 7,5 \text{ mg/cm}$

Typical plasma dynamics

optical frames and streak

W, 8x55 μm

$I_{max} = 1.5 \text{ MA}$

$\Delta t = 15 \text{ ns}$

Stainless steel, 16x100 μm

$I_{max} = 0.8 \text{ MA}$

$I_{max} = 2.3 \text{ MA}$

$\Delta t = 50 \text{ ns}$

St. steel, 16x100 μm

$I_{max} = 2.3 \text{ MA}$

58 ns

58+3,2 ns

58+6,4 ns

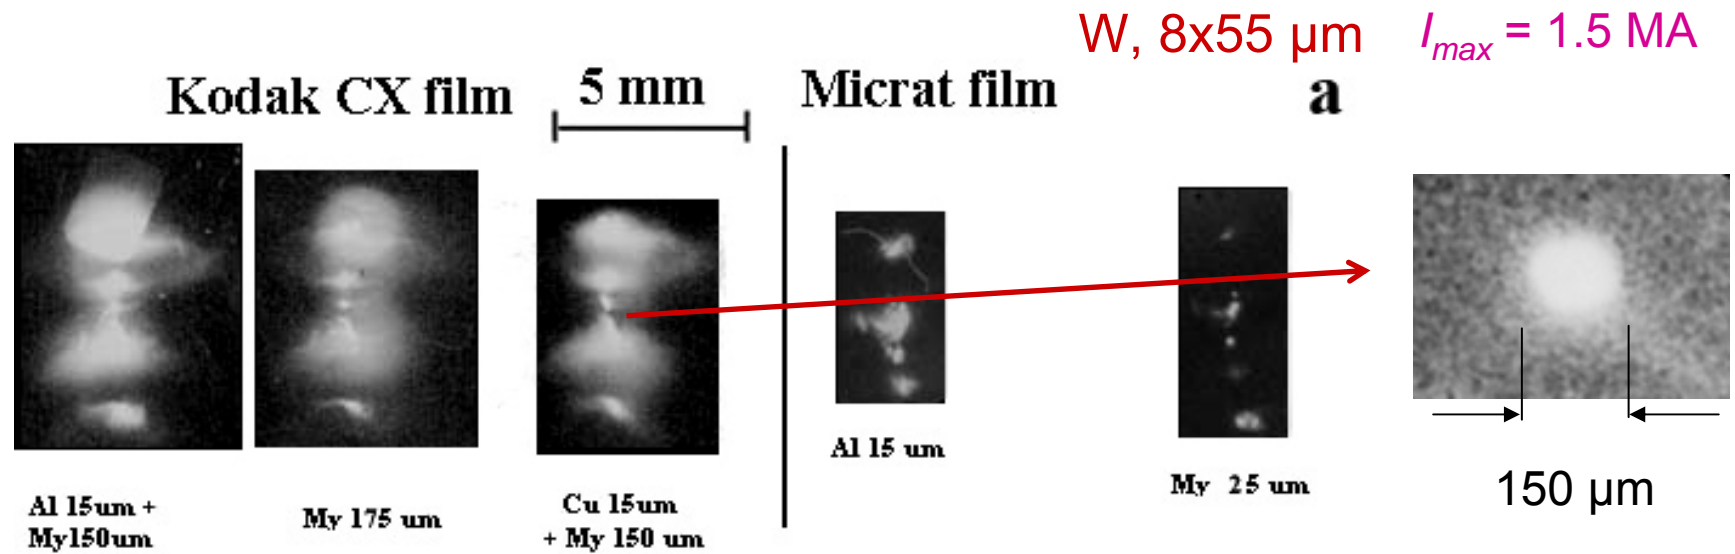

Mo, 16x70 μm $I_{max} = 2.0 \text{ MA}$

Streak image along the X pinch axis:

Mini-diode formation?

X-ray images (time-integrated pinhole)

Backside film

Frontside film

Three-channel pinhole camera with $\sim 50 \mu\text{m}$ holes, equipped with various filters. Scale 1:1.

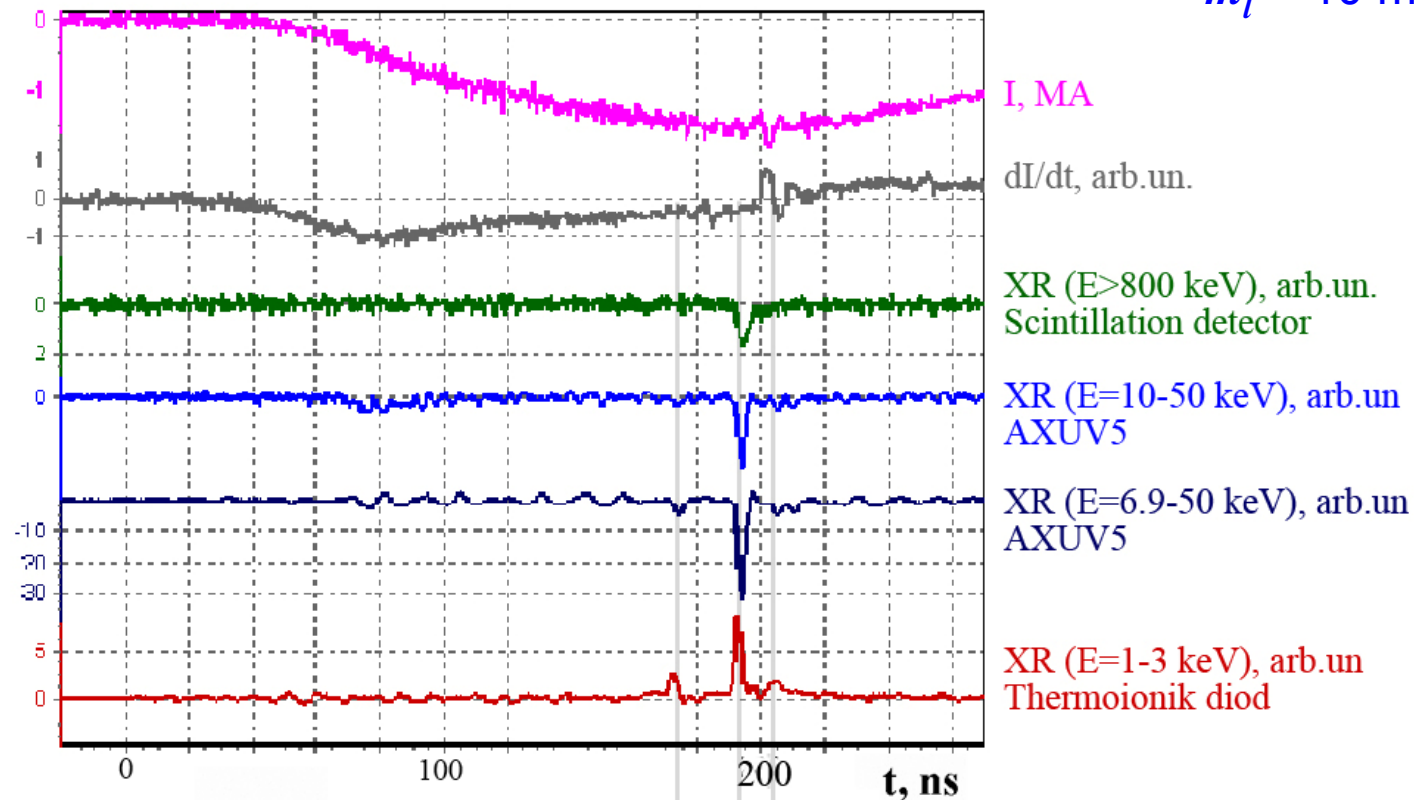

Optical streak synchronized with current and X-ray measurements

$$I_{max} = 1.7 \text{ MA}$$

Load nichrome:
16×100 μm

$m_l \sim 10 \text{ mg/cm}$

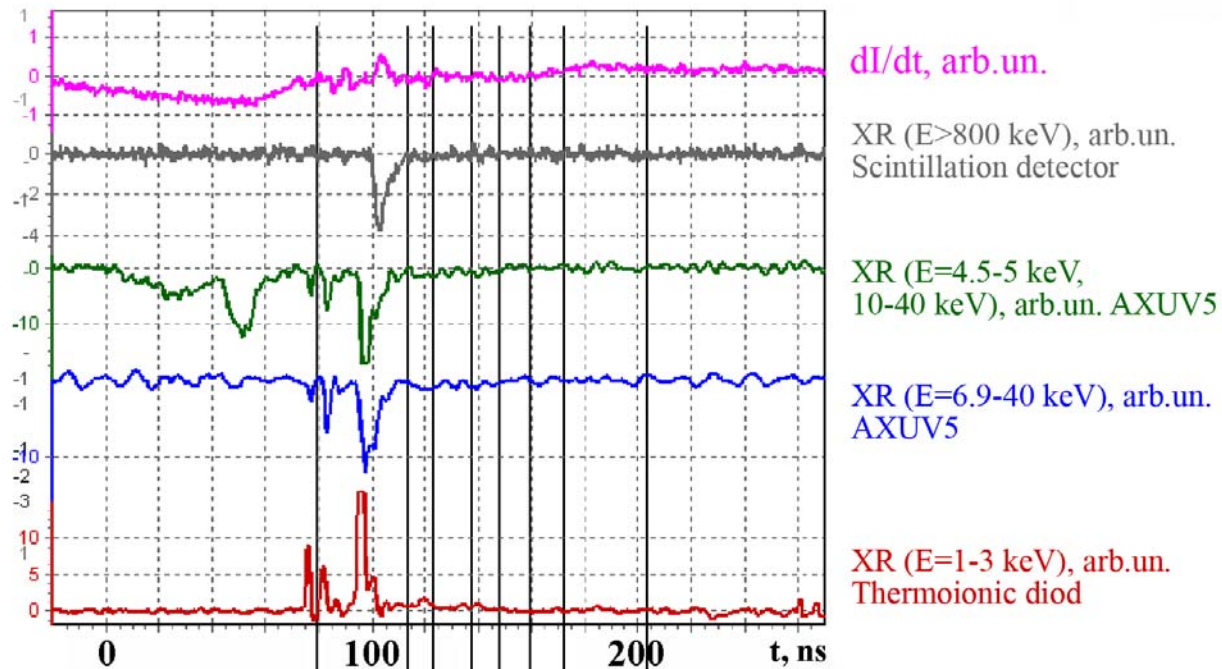

Optical streak synchronized with current and X-ray measurements

Load W: $8 \times 55 \mu\text{m}$

$m_l \sim 3,7 \text{ mg/cm}$ - «low mass»!

$I_{max} = 1.5 \text{ MA}$

Optical streak

My $25 \mu\text{m}$
Kodak CX film

Pinhole
 $5,5 - 9 \text{ keV}$
 $> 12 \text{ keV}$

Optical streak synchronized with current and X-ray measurements

Load W: 16×55 μm
 $m_l \sim 7,4 \text{ mg/cm}$

$$I_{max} = 1.5 \text{ MA}$$

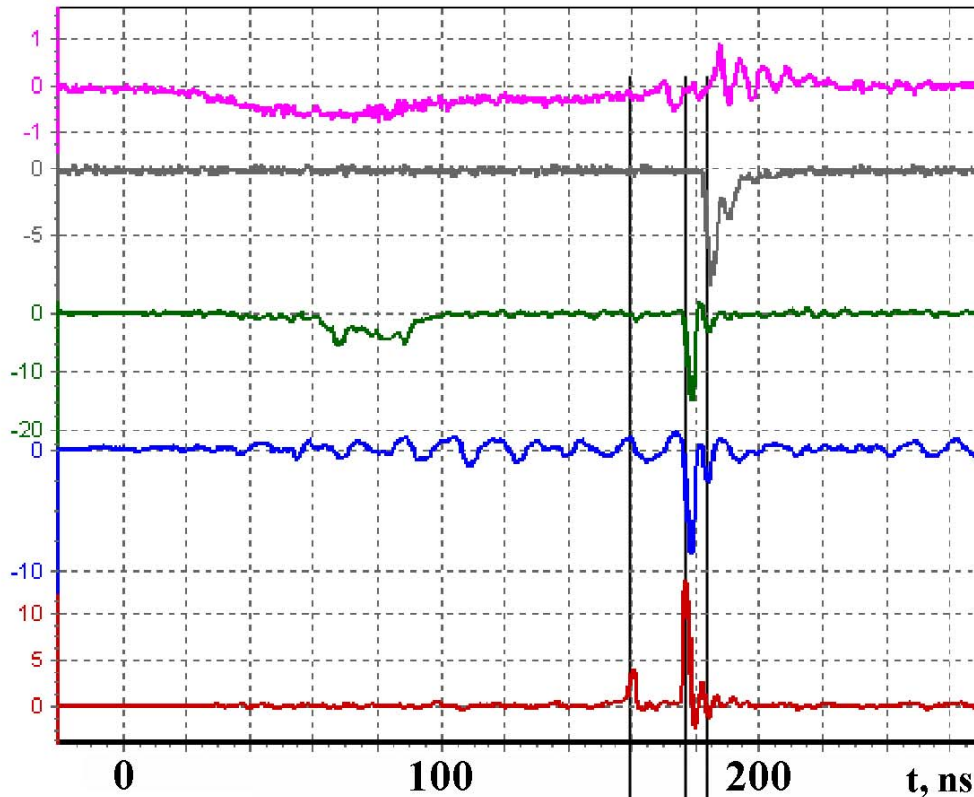

Optical streak

X-ray images, radiation dynamics and optical streak

$I_{max} = 1.9 \text{ MA}$

Load **Mo** $16 \times 100 \mu\text{m}$,
 $m_l \sim 13 \text{ mg/cm}$

XR ($E = 1\text{-}3 \text{ keV}$), arb.un.
 Thermoionic diod

Kodak CX film Micrat film

$h\nu \sim 1 \text{ keV}$

$h\nu > 3 \text{ keV}$

Line radiation

Mo, 20×70μm, $m_l \sim 7.9$ mg/cm

$I_{max} = 1.45$ MA

15 μm Cu

24 μm My

$D_{pinhole} = 50 \mu m$

Line radiation

Mo, 16×70μm $m_l \sim 6.3$ mg/cm

Energy in 2 points
2 J and 6 J

$dH = 1,2$ mm

$dX = 0,7$ mm

$T_e \sim 0.8-1.0$ keV, $n_e \sim 10^{20}-10^{21}$ cm⁻³

According to comparison with S.B.Hansen, A.S.Shlyaptseva,
S.A.Pikuz et al., Physical Review E 70, 026402 (2004).

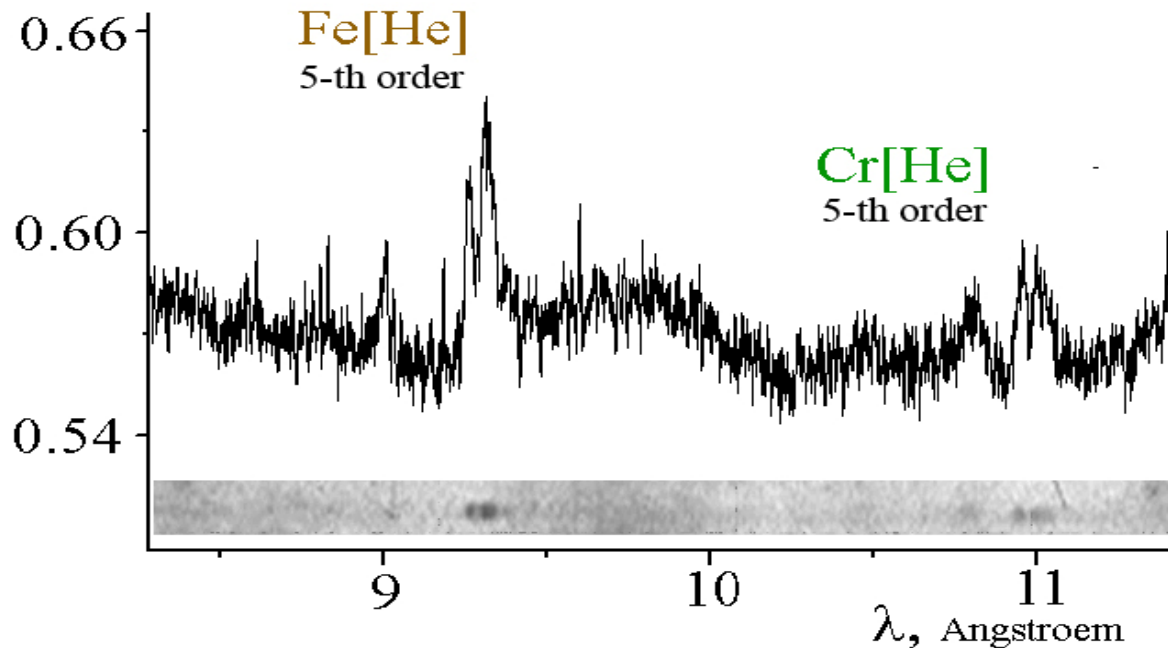

$I_{max} = 2.0$ MA

Line radiation

Stainless steel, $16 \times 100 \mu\text{m}$, $m_l \sim 10 \text{ mg/cm}$

$I_{\text{max}} = 1.75 \text{ MA}$

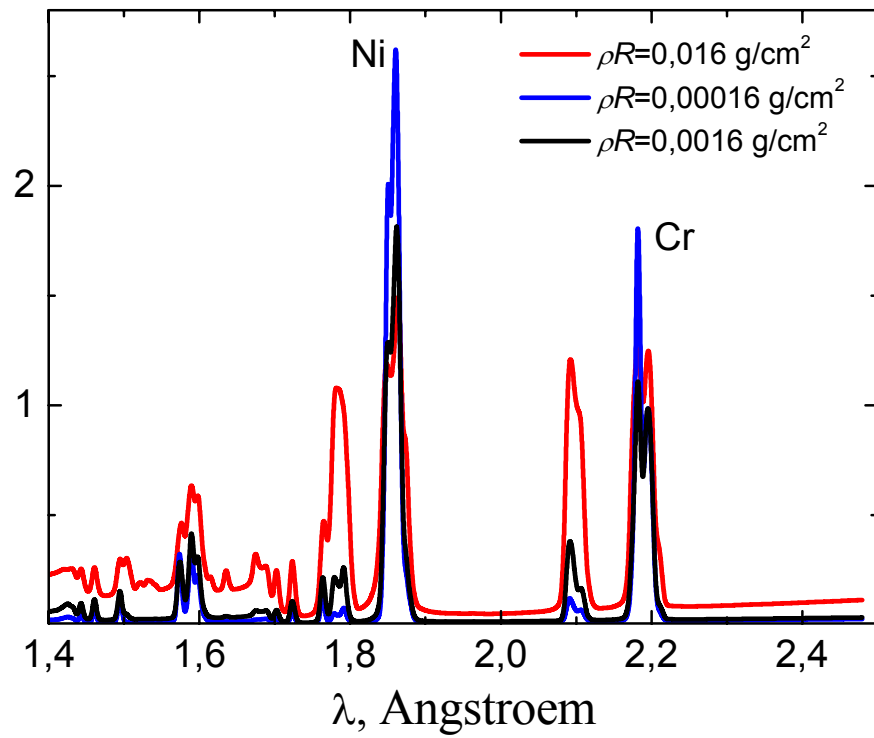

15 Cu 36 Mylar 10 μm Al

Using the experimental data 10^{18} eV of the emitted energy in the resonance He-like CrXXIII line, and calculated spectral luminosity ($\sim 10^{18} \text{ erg}/(\text{cm}^2 \cdot \text{sr} \cdot \text{s} \cdot \text{eV})$) we evaluate the emission duration to be about **7 ps**.

Plasma Parameters

Plasma Parameters

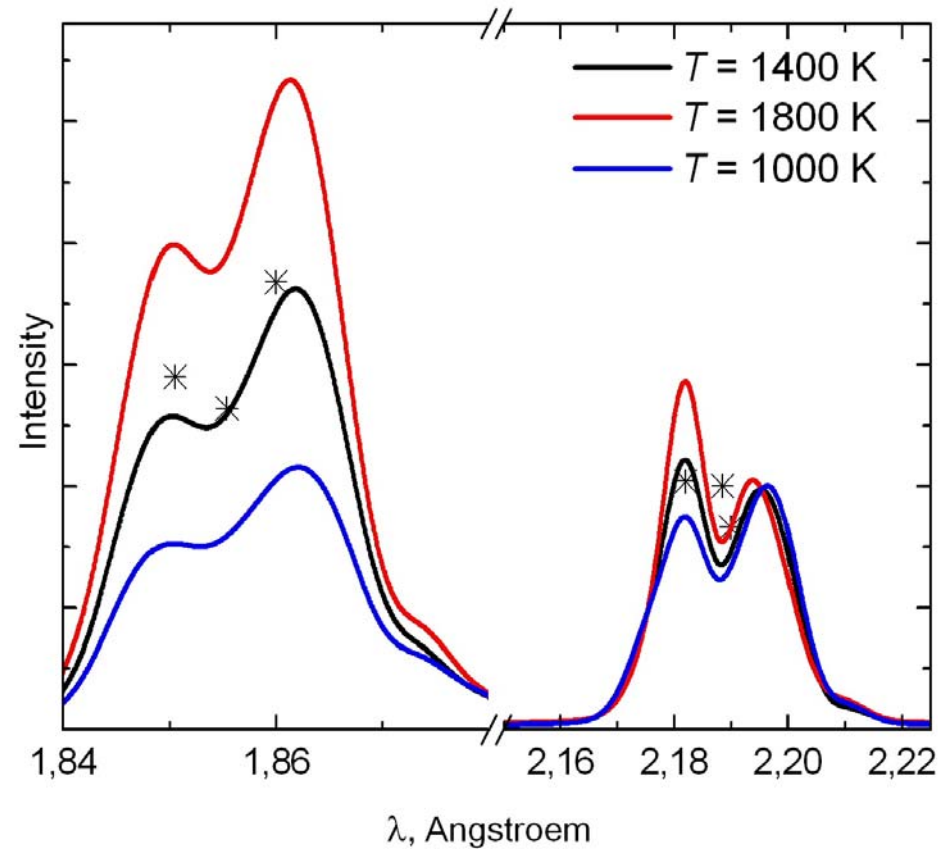

PrizmSPECT

Lines intensity ratio
modelling results:

$$T_e \sim 1200 - 1400 \text{ eV}$$

$$N_i \sim 10^{22} \text{ cm}^{-3}$$

$$d \sim 30 \mu\text{m}$$

Experimental investigations of the X-pinch have been carried out at currents up to 2.3 MA. The experimental results on high-current multi-wire X-pinch made of stainless steel, nichrome, Mo, and W, confirmed basic features of their dynamics, as well as basic statements made on the base of earlier experiments with lower current.

The total energy of Mo X-pinch radiation in the range of the quantum energy 2.5–3 keV exceeds 10 J. Direct measurements of space scales and radiated power show that the bright formation arise during the X-pinch evolution, with the brightness exceeding 10^{15} W/(cm² sr) in the range of the quantum energy 1–3 keV, by the typical linear size of the hot spot ~ 20 μ m and the radiation power ~ 120 GW. It is important to note that such extreme plasma parameters determined from the time-integrated parameters (not from those resolved in time!) have been recorded for the first time.

Using experimental data related to the energy 10^{18} eV in the spectral range $\delta E \sim 70$ eV for the resonant He-like CrXXIII line, together with the calculated hot spot space scale and the spectral brightness of the source, one could estimate the typical time of emission as $\Delta t \sim 7$ ps. Such a duration is typical of the hot spot radiation. Thus, one may conclude that the real SXR radiation power is essentially higher than that recorded by the diodes (their resolution being ~ 1 ns).

The HXR radiation of an X-pinch in the range of the quantum energy > 800 keV has been recorded and studied.
